How to use (basics)

Before you start

Before you start to set up this asset for your levels, we highly recommend to finish all roads on your scene. Because changes on level (roads on level) also requires changes in Road Navigator settings.

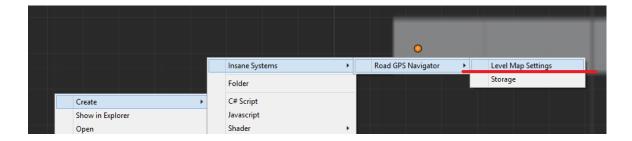

Setting up scene parameters

Setup your level with **Navigator** and **Map** is easy. First of all, you need to open folder Insane Systems -> RoadNavigator -> Prefabs.

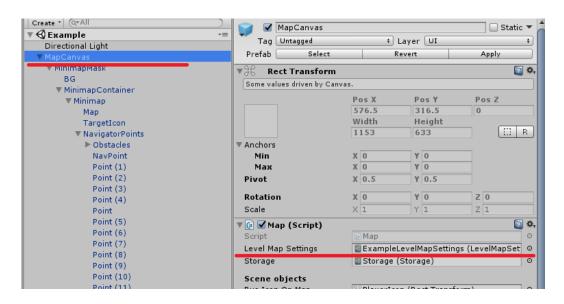

Now, bring **MapCanvas** to your Scene. This prefab is already configured with base settings, you only need to setup it for your level (you also can use **Unpack prefab** on **MapCanvas** to edit it regardless of example one).

After it is done, you need to set up **Level Map Settings**. To do it, create a new **LevelMapSettings** object by **Right Click** in the **Project window** and selecting Insane Systems -> Road GPS Navigator -> Level Map Settings.

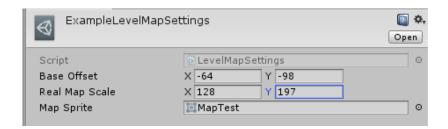

By default, this object is placed in the **Data/Levels** folder. Bring created object to scene **MapCanvas Map** component's **Level Map Settings** field:

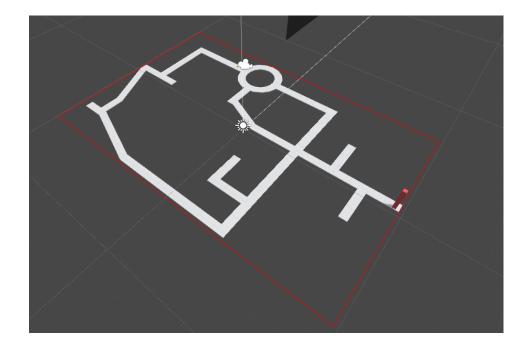

Setting up map

Now you need to edit created **LevelMapSettings** object parameters. Select it and you will see something like this:

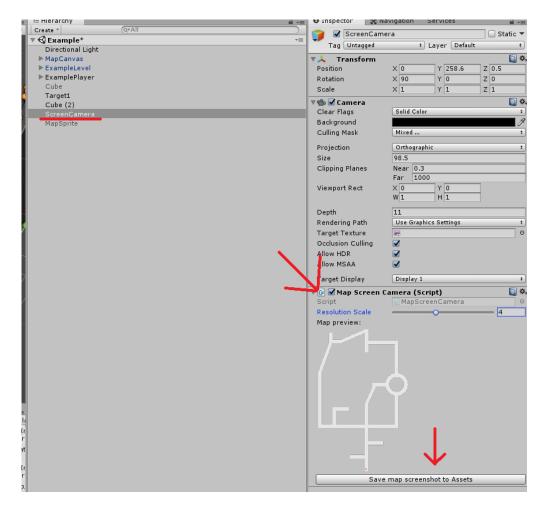

Edit this four number fields. When one of them changed, you will see **red rectangle** in **Scene** window. You need to fit your roads in this rectangle, like this:

Note that you need to fit all roads in this rect, but nothing more! It means, if you environment map is bigger than road map, put in rectangle only roads.

Now you need to make image from your map. It can be done by using our **ScreenCamera**Prefab with special component:

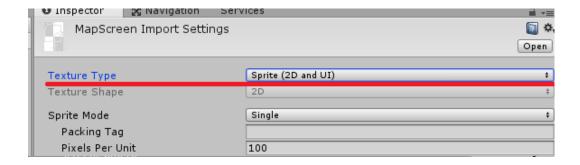

It automatically fits to parameters of **Level Map Settings** and always renders correct image of your map using Camera and RenderTexture. You can save this image by clicking **Save map screenshot to Assets**. Note that before capturing screenshot, you can disable not needed objects on map, leave only roads active.

Do it as you want, and finally, if you leave active only roads, and the camera will see the skybox below roads, the background of the map will be transparent, so it can look good on the map and navigator, try it. In our example it is done this way.

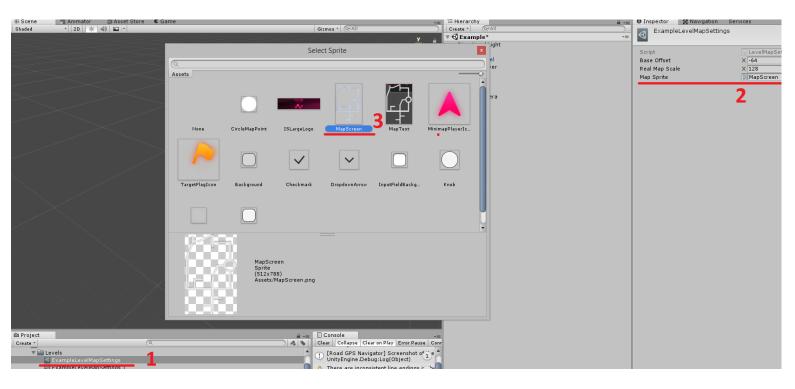

After the map image is done, you can find It in the project **Assets** folder, named **MapScreen**. You can use it as it is to finish setting up your level Navigator settings, or you can edit it in image editor, for example Photoshop (for changing visual style, etc). But in case you want to edit it, don't change image proportions, it will break the work of Navigator and Map.

Finally, to set up this image as map and navigator background, do next steps:

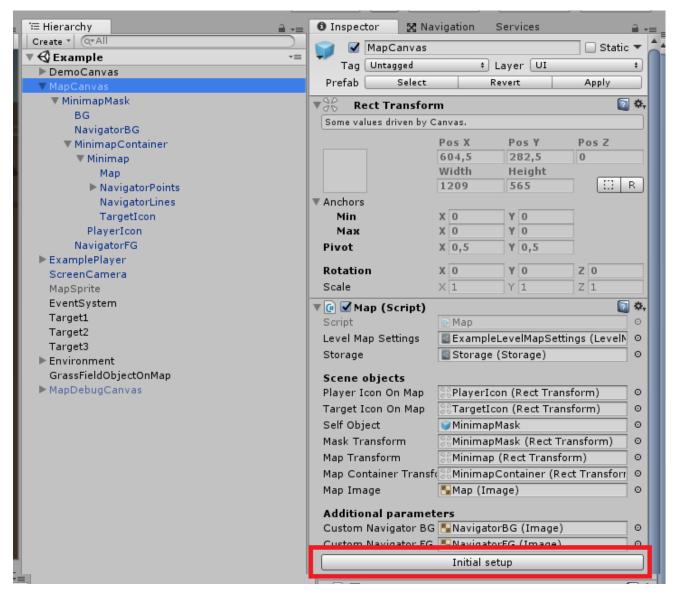

1. Mark your image as **Sprite**:

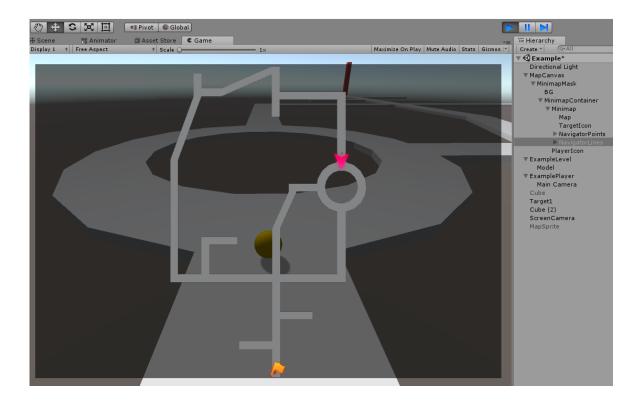

2. Select your **Level Map Settings**, and set this image to field **Map Sprite**:

3. Hit the **Initial Setup** button, it will setup new image to map and fit all map sizes in navigator for it.

4. Now you can run level and check, that map works and player position is correctly shown on map:

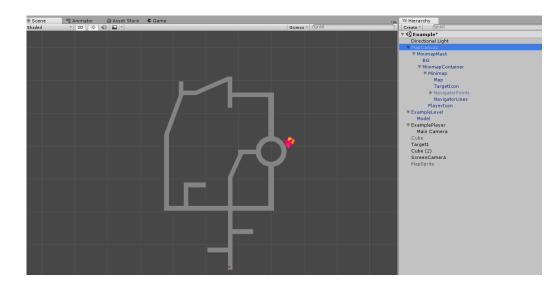

To show Map in game **press M**. (can be changed in asset settings).

If all works fine, you did everything right! Now you can go to the next step and set up **Navigator**.

Setting up roads

Initial setup button was already described above, but there some additional info.

After you use it, It will setup all **Map** and **Navigator** parameters to work with new map image and show your map image in editor:

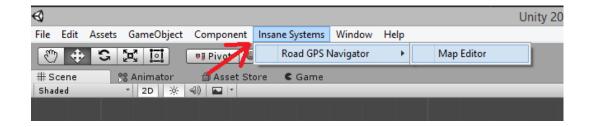

Note that you need to do it every time you change the image or its size. But if you're made a screenshot of your level when work on it is already finished and there will be no changes, you'll need to update the map screenshot only once.

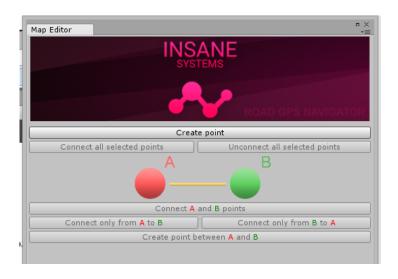

③

Now you need to **setup roads on a map**. It can done by marking all crossroads on a 2D map and connecting it similar to your roads. For big maps it can take a long time, and for this reason we made **Map Editor**, which will save your time.

To open it, move cursor to Unity top menu, and select Insane Systems -> Road GPS Navigator -> Map Editor:

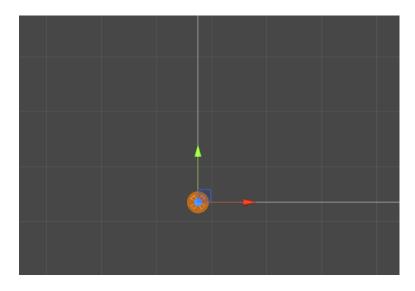

Will be opened this window:

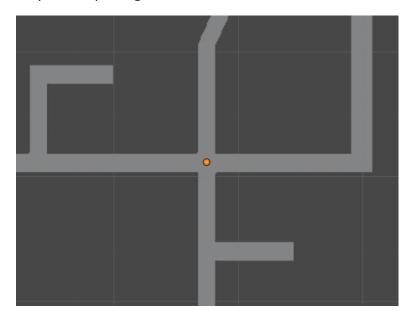

Yes, this is Map roads editor. It can look a little different in your version, because sometimes we can add some new functionality.

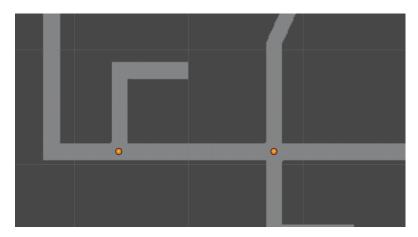

Now, let's start building roads. Better to do it by looking at your map canvas in 2D mode of Scene (Map editor will suggest you to change it if you're using 3D mode when opening it). To start, hit the **Create point** button. Result will be:

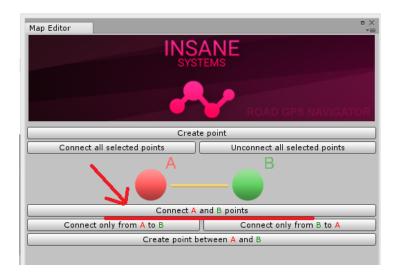

Point on **Scene** was created. This is **Navigator Crossroad Point**, described before. Now, move it to any crossroad on your map image:

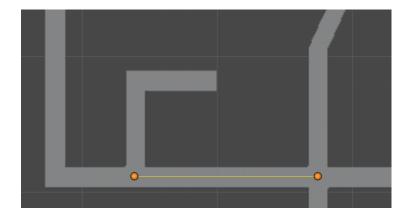

Now, create second point this way (or duplicate first point) and move to another crossroad:

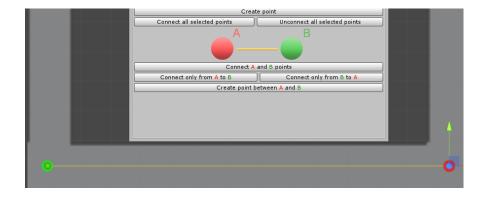

Finally, select two points and click **Connect A and B Points** in **Map Editor**:

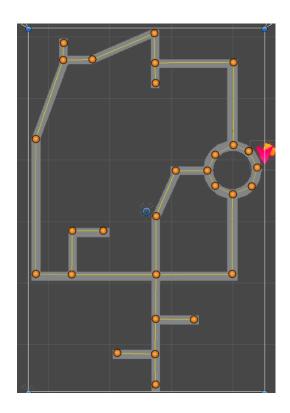

This action will create two-side connection between this crossroads (it means that now if player will be near one point, and his path will move along second point, navigator will draw line between them), you can see it in editor:

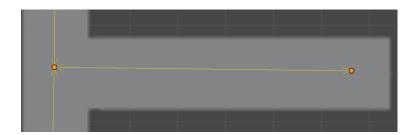

This is a road with two-side movement. To create one-side movement between two points, hit **Connect only from A to B** or **B to A button**. While editing only two points, you will see help color markers on points (red and green):

You need to connect all roads on your map this way. Finally, it can look like this (to see all connections, select **MapCanvas**):

Also, with bigger zoom you can see directions of your roads, for example two-sided:

One-sided:

Setting up Navigator Player

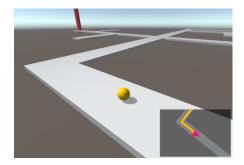

Navigator Player is a script that indicates what object the navigator should follow. It can be your player, car, etc. You need add this component to your player object:

Now, you can run the game to test your first navigator settings.

To show Navigator in game **press N**. (can be changed in the asset settings).

Navigator should work like this (captured on Asset Example scene):

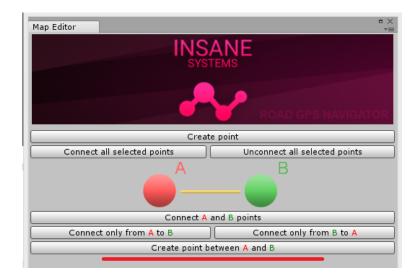

But it will not work without a target, this will be described in next partitions.

Adding detail points

If your roads contain bends, you also can add in this positions Crossroad Points, just connected to 2 other points on this road:

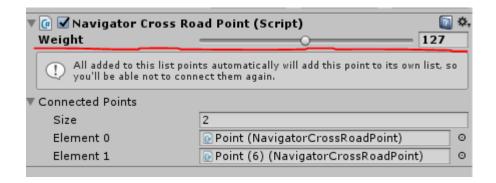

Best way to do it: select two side points and use **Create point between A and B** button in **Map Editor**:

More detailed points on the map means that the navigation line will be better quality. For example, it can be used for circle roads.

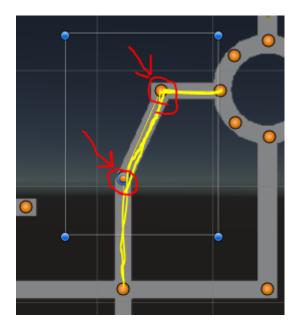

Path points weights

If you want to add priority to some road on your map, you can do it by reducing the weight of points on this road. To do it, change this parameter:

How does it works? Navigator selects 3 shortest paths from current player position, and calculates average weight of its point. Path with smaller average weight value will be selected to draw a navigation line on it. Finally, what you need to do:

1. Select key points of priority road on map:

2. Decrease their weight to value 126 or lower (127 is default value).

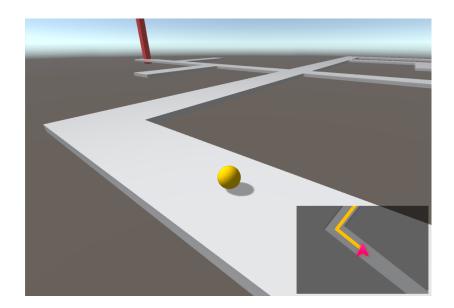

But be careful – this feature can give you wrong results, if weights will be setted up not fully correct.

Setup navigator target from code

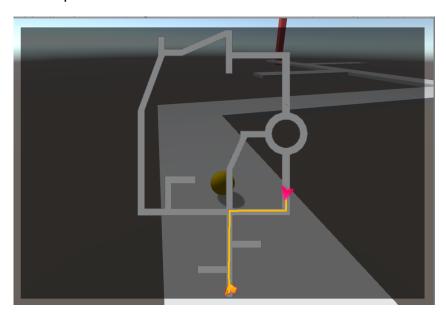

Now, when you finished with settings of all components, you will want to set targets to move on navigator from your code. It can be done very easy:

Note that you need to pass your object world position in this code, I mean the same that shown in the **Transform** component in the **Inspector**.

And final test of navigator:

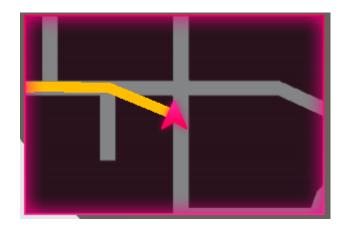

And how it looks on map:

Obstacles

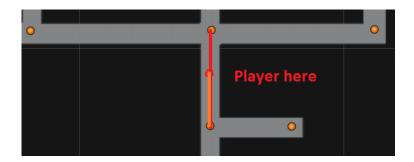

Sometimes you can notice troubles with navigator line, which looks like bug:

This happens because straight distance between player and next crossroad point is smaller, than distance between nearest to player crossroad point and next crossroad point:

Distance A bigger than Distance B (maybe this is not clear from example, but it tested and it is right), so Navigator decides to draw line from player to next point, because this will be right in this situation:

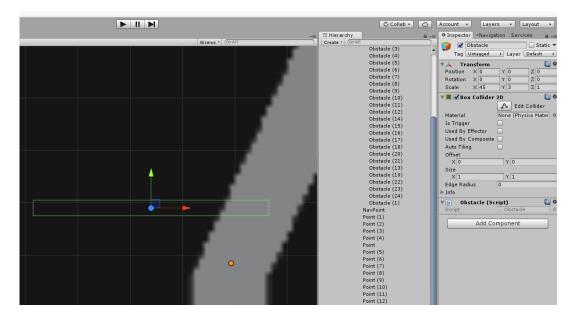

These are the same situations, but first is wrong, and second is right. To solve this problem, we added an **obstacle system**. **Obstacle** is a **Box Collider 2D** that prevents wrong situations like this.

It is <u>not necessary</u> to add obstacles, but if you will set them up, the Navigator will work better.

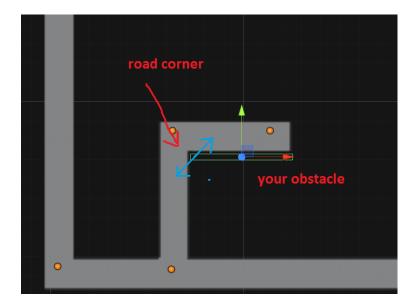

So, how should you do it? Very easy. Open **Map Editor** and hit **Create obstacle collider** button:

This action will create obstacle object on scene:

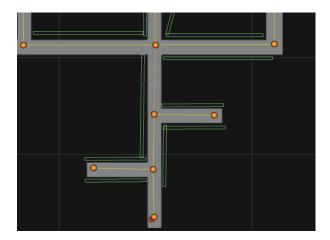

Now you can set it up by editing its **position** and **scale** transform parameters. Place obstacles on roads sides and near road corners like this:

Blue line on screenshot is possible line problems, which will be prevented. Keep it in mind and it will be easy to set up obstacles.

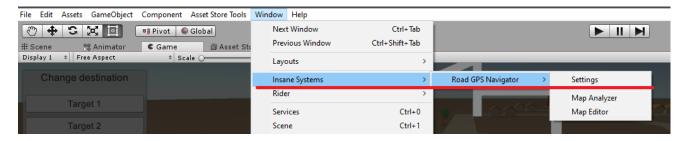

Final setup can look like this:

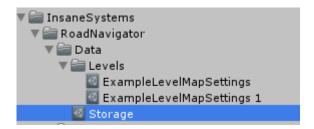

P.S.: we understand that the obstacle system looks like a workaround and we will try to improve this system to reduce time needed to get it working correctly in future updates.

Settings of Map and Navigator

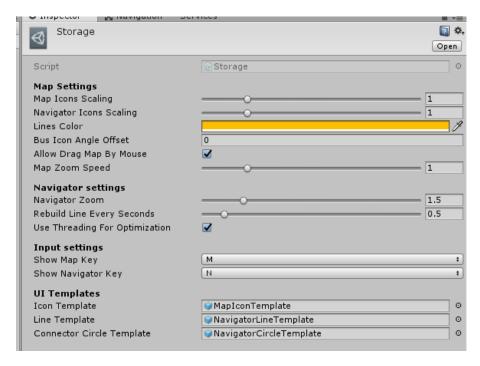

To open all global asset settings, use Unity top menu:

You also can find same asset settings in file named **Storage**:

It parameters looks like:

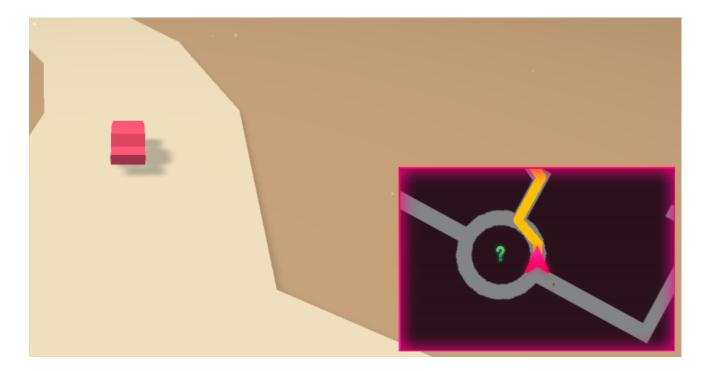

You can edit it as you want. In new updates we will extend these settings, Map Editor and other asset things.

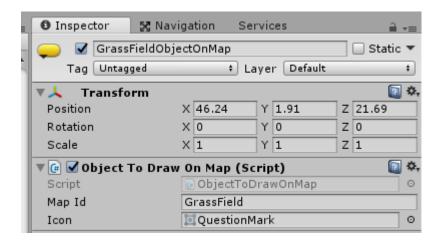

Adding custom icons to map

You can add some icons to your map, for example if your game has missions or some objects like Gas Station, Garage, etc.

How it will look (here it is question mark):

To do this, just add on any your object script named **ObjectToDrawOnMap**, and setup its parameters:

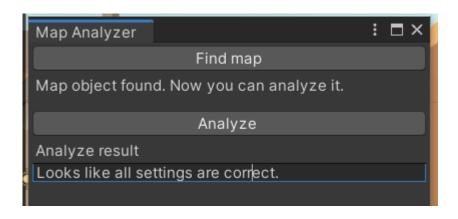

Code examples, how to add it from code and also way to remove it, if you no more want to see it on map:

Map Analyzer

Available from 1.0.6 version

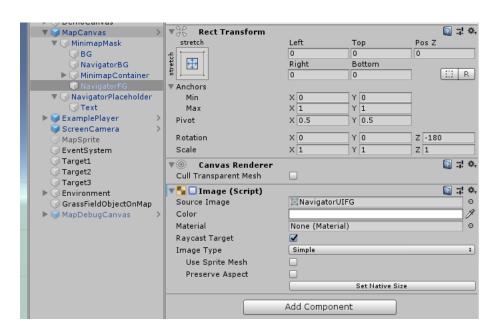

Sometimes you can miss some points when setting up the map. We have a tool named Map Analyzer, which will check all points and give you info if something is wrong in their settings.

You can find it in **Top menu -> Window -> Insane Systems -> Road GPS Navigator -> Map Analyzer**

Changing UI Style

You can edit prefab **MapCanvas** (if you've already used **Unpack Prefab** on it, it can be more comfortable to edit it) to change the style of the navigator and map.

You can edit the **NavigatorFG** object Image component to change the overlaying foreground image (in our example it is a corner image with some outline).

You also can edit the **NavigatorBG** object to edit the background color/image of the Navigator.

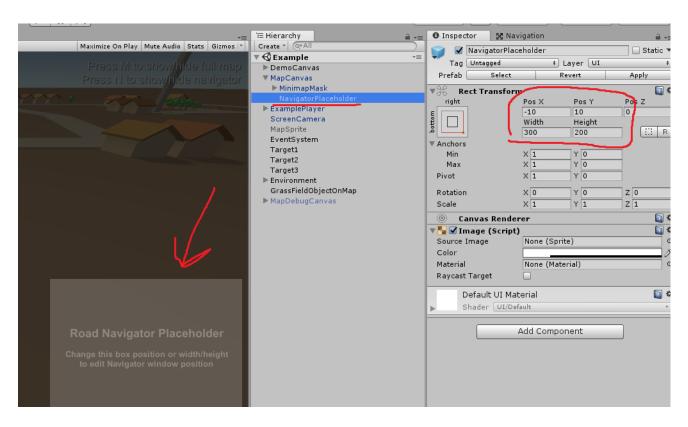

To edit a big Map background, change parameters of the **BG** object.

You also can add your own Image objects etc, but it can require code extension.

Changing UI layout

Available from 1.0.7

Possible, you want to move the Navigator window from right screen side to left, up, etc. Or maybe resize it. To do it, change Rect Transform settings (Width, height, pos X, pos Y, maybe pivot or anchors) of the **NavigatorPlaceholder** object:

Transparent box will show you the final size and position of the Navigator window.

Known Issues

D3D11: Failed to create RenderTexture (8192 x 8192 fmt 19 aa 2)

You're trying to make a too big map snapshot. Low PC specs also can affect max possible value. If you still receive this error, set a smaller map size. If it doesn't help, restart Unity.

Library package manager UI error

This error can be shown on package import in new Unity versions. You need to **remove the**Package Manager UI package from the Package Manager window to solve it.
